Key words: Urine $N_1,N_{12}$-Diacetylspermine/Urinary Bladder Cancer/ELISA

Background: $N_1,N_{12}$-diacetylspermine, a diacetylpolyamine which was recently identified in urine, appeared to be a useful tumor marker for a number of cancers. No valid data on urine diacetylspermine concentration in patients with urinary bladder cancer exist.

Aim: Evaluation of urine $N_1,N_{12}$-diacetylspermine concentrations in individuals with urinary bladder cancer.

Methods: Urine samples were used from 36 patients with urothelial tumors of the urinary bladder and from 30 patients with benign urological diseases. Urine was collected before cystoscopy. Enzyme-linked immunoabsorbent assays (ELISA) were performed for diacetylspermine from urine.

Results: Urine diacetylspermine did not differentiate in individuals with urinary bladder cancer from controls (medians 171.5 vs 143.8, $p = 0.64$). Its efficacy for urinary bladder cancer detection was not shown.

Conclusions: Urine $N_1,N_{12}$-diacetylspermine is probably not a useful marker for urinary bladder cancer.

INTRODUCTION

Urothelial urinary bladder cancer is a disease with a variable clinical course. Cystoscopy and cytology are standard methods used in diagnosis and follow-up of tumors of the urinary bladder. Cytology requires correct sample processing and is a highly subjective interpretation done by a cytopathologist. Results are available minimally after 24 hours and display a low specificity (40–60 %). Cystoscopy is uncomfortable, the hence other methods are being tested.

To date, several papers have been published on examination using several laboratory markers (e.g. measurement of TPS, BTA, telomerase, NMP22, M344, chromosomes aneuploidy, survivin, livin, midkine, endostatin). Although the first studies reported on decreased frequency of cystoscopic examinations and satisfactory diagnostic sensitivity and specificity of these markers, further investigations failed to confirm the promising conclusions. The markers were found only to supplement cystoscopic examination, not replace it.

In addition, interpretation of any laboratory marker in clinical practice comprises a false positivity of results. This may be associated with the presence of tumor cells in urine released from a tumor, which is as yet endoscopically occult. There is sporadic information about the comparison of the course of disease in positive and false-positive patients. Therefore, additional markers are being sought after.

The aim of our study was to test the diagnostic efficacy of a new potential hypothetic cancer marker – diacetylspermine concentrations in the urine individuals with urinary bladder cancer.

MATERIAL AND METHODS

The project was designed as a prospective blind study. 69 patients of the Urology Clinic Department at the Olomouc Faculty Hospital were evaluated. 66 subjects were selected (mean age 63.1 years). They were divided into 2 groups:

1st group - 36 patients with endoscopic and histologic urinary cancer bladder confirmation

2nd group - 30 patients with benign urologic disorders and negative cancer anamnesis.

Sampling

Urine was sampled before cystoscopy and tested for urine microscopy, cytology and frozen for diacetylspermine measurement.

ELISA for diacetylspermine

The human ELISA kits were obtained from Biovendor Laboratory Medicine, Inc. (Brno, Czech Republic). The assay was conducted according to the manufacturer’s instructions. The intra-assay and inter-assay variations were
D. Stejskal, V. Humenanska, Z. Hanulova, R. Fiala, R. Vrtal, P. Solichova, M. Karpisek evaluated by measuring 3 different samples in 10 replicates (CV intra-assay < 5 %, CV inter-assay < 7 %, detection limit 3 nmol/l).

Statistical analysis
The data were processed by means of the software Medcalc (Medcalc, Mariakerke, Belgium). P < 0.05 was considered as statistically significant. The comparison of cancer marker values between subjects with and without cancer diagnosis was made using a Mann-Whitney test (for none normal data distribution) and independent t test (normal data distribution). ROC curves for normal data distribution and frequency table with chi-square for none normal data distribution were performed. All the data are expressed as medians and means ± S.D.

RESULTS
Urinary values of diacetylspermine did not differ in individuals with urinary bladder cancer and controls (medians 171.5 vs 143.8, p = 0.64), efficacy was not sufficient (AUC < 0.7) (Tab. 1–2, Fig. 1).

DISCUSSION
Cell growth is dependent on a sustained supply of polyamines, which is typically met by the integrated contributions of biosynthesis, catabolism, uptake, and export, each of which is sensitive regulated by effector molecules that, in turn, are controlled by intracellular polyamine pools. Thus, ornithine decarboxylase and S-adenosylmethionine decarboxylase control biosynthesis, a polyamine transport system modulates uptake, and spermidine/spermine N1-acetyltransferase regulates polyamine catabolism and export from the cell. Neoplastic cell growth is associated with elevated polyamine biosynthetic activity, even when the surrounding normal tissue itself is rapidly proliferating15–17.

N1,N12-diacetylspermine (DiAcSpm) is a minor component of human urinary polyamine to which little attention has been paid until recently. Excretion of this diacetylpolyamine, in particular, into urine is frequently and markedly increased in association with all types of cancer (prostate, breast, colon, etc.). Remission is usually accompanied by recovery of urinary diacetylpolyamine to normal level. Diacetylspermine is more sensitive than CEA, Ca 19-9 and Ca 15-3 for detecting colorectal and breast cancer13, 14. More importantly, diacetylspermine ef-

Evaluation of urine N1,N12-diacetylspermine as potential tumor marker for urinary bladder cancer

N1,N12-diacetylspermine is also involved and the possible roles of diacetylspermine role in urinary bladder cancer expansion was found in the literature.

An ELISA procedure for rapid determination of diacetylspermine was recently developed to promote the clinical application of this new tumor marker. Results of our paper did not confirm the hypothesis about this marker use in clinical urinary bladder cancer diagnosis.

It is concluded that individuals with urinary bladder cancer did not differ in urine N1,N12-diacetylspermine values from healthy controls. Our data suggest, for the first, that urine diacetylspermine is not the sufficient marker for bladder cancer diagnosis.

ACKNOWLEDGEMENT

This study was supported by JGA grants NR/8402 a NR/8442 from the Ministry of Health of the Czech Republic.
