Key words: Glucan/Indomethacin/Adverse effects/Phagocytosis/IL-6/Glucose

Background: The most important quality of β-glucans and the reason why so much attention has been devoted to them are their physiological effects. They are typical biological response modifiers with pronounced immunomodulating activity. However, some questions about possible side effects remain.

Aim: Several papers reported the lethal side effects of non-steroidal anti-inflammatory drugs in glucan-treated mice, probably due to the peritonitis by enteric bacteria. However, these results were never independently confirmed. The purpose of this study is to evaluate these claims using several different types of glucans.

Methods: Effects of combined treatment with four different types of glucans and indomethacin were measured by evaluation of phagocytosis of HEMA particles by peripheral blood leukocytes and production of IL-6 in mouse serum. In addition, the level of blood glucose, colon length and survival after 30 days of treatment was measured.

Results: Our finding showed that simultaneous treatment with glucan and indomethacin caused a small decrease of phagocytic activity and IL-2 production. Two other tested parameters—blood glucose levels and colon length—that had been found to be significantly affected by this treatment, were virtually unchanged. In the final, yet most important part of the study, we found absolutely no mortality, regardless of the type of glucan or the routes of glucan administration.

Conclusion: No adverse negative effects due to simultaneous treatment with glucan and non-steroidal anti-inflammatory drug dose was found, despite testing two different routes of glucan administration and four different types of glucan.

INTRODUCTION

Indomethacin is a non-steroidal anti-inflammatory drug suppressing prostaglandin synthesis via inhibition of cyclooxygenase. Despite well known positive effects, adverse side effects including mucosal damage on the gastrointestinal tract exist1,2.

β-Glucans are natural immunomodulators gaining significant interest from both the scientific community and the general public. These polysaccharides are non-cellulolic polymers of β-glucose, with glycosidic bonds in position β(1→3) and with certain portion of β(1→6) branched glucose molecules. They are isolated mainly from various fungi, but they are also present in other sources, such as cereals, bacteria or seaweed. These compounds, isolated from different sources that otherwise caused similar or nearly identical immune reactions in macroorganisms, can differ in their primary, secondary or tertiary structures or their solubility in water or alkalies (for review see3).

The most important quality of β-glucans and the reason why so much attention has been devoted to them are physiological effects that they reveal. They are typical biological response modifiers with pronounced immunomodulating activity. In addition, over 6,000 scientific papers have been devoted to biological actions of glucans.

Thus far, the strong immunostimulating properties of glucan are the best studied effects. The best known effects of β-glucans consist of the augmentation of phagocytosis of professional phagocytes – granulocytes, monocytes, macrophages and dendritic cells. In this regard, macrophages, considered to be the basic effector cells in host defense against bacteria, viruses, parasites and tumor cells, play the most important role4.

Decade of studies of the Ross group help to elucidate the mechanisms of the glucan action. Our research has shown that CR3 serves as a major receptor for β-glucans with human5 or mouse4 leukocytes and is probably responsible for reported functions of β-glucans. β-Glucan specifically targets macrophages, neutrophils, and NK cells to tumors that are opsonized with antibodies and complement. Thus, β-glucan has the same specificity as the tumor-opsonizing antibodies. Studies in mice have shown the therapeutic value of small soluble β-glucans (5-20 kD) that can bind to CR3 monogamously and prime the receptor for subsequent cytotoxic activation only if membrane CR3 are subsequently clustered by contact with the clustered iC3b coating a tumor cell. High m.w. soluble β-glucans such as lentinan (> 500 kD) that have been used for patient therapy are large enough to cross-link and cluster membrane CR3, triggering respiratory bursts, degranulation, and cytokine release in the absence of tumor target cells6,7. Several studies have shown the safety of soluble β-glucans and the absence of side effects. It should further be noted that small soluble polysaccharides are rarely antigenic unless coupled to proteins.

Our knowledge of possible negative effects of various β-glucans is limited. Particulate β-glucan applied parenterally was reported to cause granuloma formation, micro-embolization, local inflammation and pain8,9. Inhalation
of intact cells or cellular detritus of fungi or yeasts—in
gredients of home dust\(^{10}\) or different agricultural and indus-
trial dusts\(^{11}\)—induces the so called syndrome of toxic
organic dust which is characterized by lung reactions that
include pneumonia, cough, chronic bronchitis\(^{12}\), rhinitis,
headache and irritation of eyes and throat. \(\beta\)-Glucans were
reported as important causal factors of these complaints\(^{13}\)
which, through activation of macrophages, monocytes
and leukocytes, causes increased secretion of inflam-
matory components (e.g., TNF-\(\alpha\) and interleukin-8 (IL-
8)). \(\beta\)-Glucans have also been suggested to be important
agents in the inflammatory reactions seen in the so called
Sick Building Syndrome\(^{14}\).

A major problem was evidenced when glucan was
applied simultaneously with indomethacin. Several pa-
ers reported the lethal side effects of indomethacin in
glucan-treated mice\(^{15-18}\). These authors found that in glu-
can–treated mice, non-steroidal anti-inflammatory drug
caus\[ed a gastrointestinal damage resulting in peritonitis
by enteric bacteria and subsequent death. The findings
that lincomycin protected the animals from septic shock
in these glucan-indomethacin model further supported
the theory of bacterial infection. However, these results
were never independently confirmed. The purpose of this
study is to evaluate these claims using several different
types of glucans.

**MATERIALS AND METHODS**

**Animals**

Female, 6 to 10 week old BALB/c mice were pur-
chased from the Jackson Laboratory (Bar Har-
bor, ME). All animal work was done according to the University of
Louisville IACUC protocol. Animals were sacrificed by
CO\(_2\) asphyxiation.

**Material**

RPMI 1640 medium, sodium citrate, Wright stain,
and indomethacin were obtained from Sigma Chemical
Co. (St. Louis, MO), fetal calf serum (FCS) was from
Hyclone Laboratories (Logan, UT).

\(\beta\)-1,3 glucans

The glucans used in this study were purchased from
the following companies: NOW BETA glucan from NOW
FOODS (Bloomington, IL), Epicor from from Embria
Health Sciences (Ankeny, IA), Glucan #300 from Transfer
Point (Columbia, SC), and Glucagel T from GraceLinc
(Christchurch, New Zealand).

**Glucan treatment**

Individual glucans were applied either intraperito-
neally or orally. The samples were collected at different
intervals after either ip. injections (100 \(\mu\)g of glucan/
mouse) or after feeding with glucan-containing diet. All
diets (Laboratory Rodent Diet 5001 enhanced with vari-
ous doses of glucan) were formulated and prepared by
Purina (Richmond, IN). Diet ingredients for all groups
were identical except for the proportion of glucan.

**Phagocytosis**

The technique employing phagocytosis of synthetic
polymeric microspheres was described earlier\(^{19}\). Briefly:
peritoneal cells were incubated with 0.05 ml of 2-hydroxy-
ethyl methacrylate particles (HEMA; 5x10^8/ml). The test
tubes were incubated at 37\(^\circ\) C for 60 min., with intermit-
tent shaking. Smears were stained with Wright stain. The
cells with three or more HEMA particles were considered
positive. The same smears were also used for evaluation
of cell types.

**Cytokine assay**

BALB/c mice were intraperitoneally injected with
100 \(\mu\)g of glucan and fed with indomethacin. Control
mice obtained PBS only. After 24 hrs, the mice were
sacrificed and blood was collected in Eppendorf tubes.
Subsequently, the serum was prepared, collected and
stored at -80 \(\circ\)C for no more than 1 week. Alternatively,
100 \(\mu\)g/mouse in PBS) were administered ip.
3 times on days -5, -3, and -1. Indomethacin (5 mg/kg)
was administered p.o. from day 0 to 5.

The levels of IL-6 in serum samples were evalu-
ated using a commercial kit OptEIA Mouse IL-6 set
(Pharmingen, San Diego, CA, USA) according to the
manufacturer’s instructions. The optical density was
determined using a STL ELISA reader (Tecan U.S.,
Research Triangle Park, NC) at 450 nm with a correc-
tion at 570 nm. Data shown were calculated from the
standard curve prepared by the automated data reduction
using linear regression analysis. A standard curve was run
with each assay.

**Gastrointestinal length**

The entire colon, from the coecum to the bottom of
the rectum, was removed and colon length was measured
as an indirect marker of inflammation\(^{18}\).

**Glucose**

Mice were deprived of food for 24 hr and sacrificed.
Serum was collected via the retro-orbital sinus and stored
at -80 \(\circ\)C for less ten a week. Biochemical analyses were
performed by Antech Diagnostics (Indianapolis, IN).

**Survival experiments**

In Group A, glucan was injected at days -5, -3 and -1,
indomethacin in delivered water from day 1 to day 30.
In Group B, same doses of glucan and or indomethace-
ines were delivered orally from day 1 to day 30. The mice were
observed daily and survival was counted. The experiment
was stopped after 30 days.

**RESULTS**

The number of individual glucans is almost as great as
the number of sources used for their isolation. The ration-
ale for this combination of glucan samples was not only
their commercial availability and success but, most im-
portantly, we tried to include both soluble and insoluble
β-Glucan-indomethacin combination produces no lethal effects

Glucans and also glucans from different sources, including yeast, mushrooms and cereals.

Glucans are generally considered to be potent stimulators of cellular immunity, with macrophages and neutrophils being the most important targets. Not surprisingly, we started our evaluation of glucan activities by phagocytosis. We used the synthetic polymeric microspheres, HEMA, since their use, dose, and timing are already well established in glucan studies. Results summarized in Fig. 1 show significant effects of glucans #300 and Now on encapsulation of synthetic particles by peripheral blood neutrophils. At the same time, indomethacine significantly lowered the phagocytic activity. However, three glucans—#300, Now and glucage—returned this suppression to almost normal values.

Next, we measured the level of IL-6 in serum of mice treated with glucan and indomethacin for 24 hr. Results summarized in Fig. 2 show that all glucans stimulated the IL-2 secretion. The simultaneous addition of indomethacin resulted in small and, in most cases, insignificant suppression of IL-6 secretion. The suppression was significant, only in the case of Now glucan. Longer exposure to glucans resulted in higher IL-6 secretion (Fig. 3) and longer exposure to indomethacin resulted in lower IL-6 production. Glucans #300 and Epicor managed to buffer the indomethacin-induced suppression.

Serum glucose concentrations of glucan-treated mice was compared with those treated with glucan- and indomethacin. On day 5, mice were sacrificed and sera were collected. As shown in Fig. 4, the serum glucose levels were not significantly affected by either glucan alone or by indomethacin alone.

Intestinal injury is common in indomethacin-treated subjects and colon shortening is considered to be a characteristic sign of the inflammatory bowel disease. Therefore, we measured effect of glucan and/or indomethacin on the colon length. Glucans (100 μg/mouse in PBS) were administered i.p. 3 times on days -5, -3, and -1, indomethacin (5 mg/kg) was administered p.o. from day 0-to-5. Colons were obtained from each group and measured on day 5. Glucan alone had no effects on colon length. Similarly, indomethacin alone caused no colon shortening. When combined, no shortening of the colon was observed. Conversely, simultaneous treatment with Epicor and indomethacin resulted in significant increase of colon length.

Finally, we addressed the most important question—does the simultaneous treatment of mice with glucan and indomethacin really affect the lethality? To examine the effect of this combination, we measured the mortality of animals after 30 days of treatment. Results given in Table 1 showed that, regardless of the administration of the glucan, absolutely no changes in mice survival were found.

DISCUSSION

β-Glucans belong to a group of natural, physiologically active compounds, generally called biological response modifiers.

The best known effects of β-glucans consist of the augmentation of phagocytosis of professional phagocytes, granulocytes, monocytes, macrophages and dendritic cells. Activation of macrophages and other professional phagocytes represents an element of more complicated processes, when mediator molecules secreted by them (such as IL-1, IL-9, or TNF-α) initiate inflammation reactions. Additional studies established that glucans also stimulate the humoral branch of immune reactions. In addition, glucans were repeatedly shown to overcome the immunosuppression, caused by either irradiation or chemotherapy.

The rationale for the choice of glucans parallels what was stated in our previous paper. We chose four glucans that are widely sold and available in the US, Europe and the Far East, representing grain-, mushroom- and yeast-derived glucans in partly soluble and insoluble form. Briefly, #300 is insoluble yeast-derived glucan; Glucagel is barley-derived glucan; NOW is a mixture of both insoluble glucans from yeast and soluble glucans from mushrooms; and Epicor is a partly soluble yeast-derived glucan.

Despite the fact that most reports found no significant side effects connected with glucan treatment (for review see), including long-term use. One potential question remains—are there lethal side effects when glucan is combined with indomethacin? Several reports described that β-glucan-induced inflammatory processes could competitively interact with simultaneously administered nonsteroidal antiinflammatory drugs. The lethal toxicity due to septic shock, elicited by a sequential administration of β-glucan and a nonsteroidal anti-inflammatory drug indomethacin, was described in mice. In addition, these effects can be reversed by antibiotics. Unfortunately, all these reports are from one laboratory and despite the

Fig. 3. Role of glucans and indomethacin on the level of IL-6 in serum 5 days after application of tested substances. Glucan (100 μg/mouse in PBS) was administered ip. 3 times on days -5, -3, and -1. Indomethacin (5 mg/kg) was administered p.o. from day 0 to 5. *Represents significant differences between group without indomethacin and group with indomethacin at P ≤ 0.05 level.

Fig. 4. Role of glucans and indomethacin on the level of glucose in serum 5 days after application of tested substances. Glucan (100 μg/mouse in PBS) was administered ip. 3 times on days -5, -3, and -1. Indomethacin (5 mg/kg) was administered p.o. from day 0 to 5.

Fig. 5. Glucan (100 μg/mouse in PBS) was administered ip. 3 times on days -5, -3, and -1. Indomethacin (5 mg/kg) was administered p.o. from day 0 to 5. Colon lengths were obtained from each group and measured on day 5. Number of mice used in each group was 3.

fact that these effects were repeatedly described for more than 10 years, they were never independently confirmed. The aim of this report was, therefore, to either confirm or reject the current hypothesis about the negative association of glucan and non-steroidal anti-inflammatory drugs.

We have used the same conditions as described in18. In order to be sure we evaluate all possibilities, we included the experimental group where glucan was also administered orally. In addition, as individual glucan often differ in their biological properties, we wanted to establish that our findings had general meaning. Therefore, we used four different types of glucan, differing in source, solubility and activity.

Our finding showed that simultaneous treatment with glucan and indomethacin caused small decrease of phagocytic activity and IL-2 production. Two other tested parameters—blood glucose levels and colon length—both found to be significantly affected by this treatment18, were
induces a cytotoxic effect upon tumor cells and shows properties. Function of formed nitric oxide is double-edged. It is synthesized, the availability of L-arginine, formation of cGMP by soluble guanylate cyclase, and the overall extra vasodilatation brings about an intense drop of venous resistance and blood pressure. Other side effects imputed to β-glucan-induced nitric oxide production are bioaerosol-induced respiratory symptoms seen in both occupational and residential environments. Generally, the bioaerosol-induced respiratory symptoms seen in both occupational and residential environments. Generally, the vasodilatation results in vasodilatation of veins. The vasodilatation brings about an intense drop of venous resistance and blood pressure. Other side effects imputed to β-glucan-induced nitric oxide production are bioaerosol-induced respiratory symptoms seen in both occupational and residential environments. Generally, the dual role of NO as a protective or toxic molecule is due to several factors such as the isoform of NO involved, concentration of NO and the type of cells in which it is synthesized, the availability of L-arginine, formation of cGMP by soluble guanylate cyclase, and the overall extra and intracellular environment in which NO is produced. It is important to note that there are some limitations of this study, as some of the observed markers are not full markers of sepsis (e.g. glycemia). Similarly, colon length is not by some considered to be an adequate marker of inflammation. However, the most important result of our study was the finding of absolutely no lethal effects of the glucan-indomethacin combination, making the relevance of the supporting markers significantly less relevant. There are two problems with natural β-glucans that make them undesirable as drugs. First, there is considerable variation in the structure of β-glucans isolated from the same strain of fungi. The second problem in the development of a drug from a natural product is that it is difficult to make it proprietary and protect the investment required for development. However, based on results of this study, the adverse negative effects of the simultaneous treatment with glucan and non-steroidal anti-inflammatory drugs does not seem to be another problem.
